In order for the grand campaign extension to run properly, you must follow these directions to reinstall VASSAL and allow it to use more memory:

1. Go to http://www.vassalengine.org/InstallVASSAL.jar

2. Open the file (do not save it)

3. You will now be in the setup window. Choose the most recent version of VASSAL to install (2.9 as of this writing).

4. **VERY IMPORTANT** You will now be asked to choose the memory allocation for VASSAL. The default is set to 256MB. This extension will *not* work at that setting. You need to select 512MB at a minimum. 1GB is even better if you think your computer is up to the task.

5. Follow the rest of the prompts to install VASSAL.

Now, if you've never used an extension for a VASSAL module, keep reading.

1. Go to the folder where your GTC module is stored. For now we'll assume it's in C:\Program Files\VASSAL\Modules.

2. Create a new folder and name it "xxx_ext" where xxx = the name of your GTC module. For example, if it's called GTC, then the extension folder should be named GTC_ext. Don't worry about the .zip or .mod in the module name, you can leave that part out.

3. Put the extension in this new folder. It will automatically load when you run the GTC module *as long as* it is in the same folder where the primary module is stored.

I hope this is clear to everyone. If not, shoot me an email at rfdoane@yahoo.com and I'll help out as best I can. Enjoy!
